LOGARITHMIC STRUCTURES OF FONTAINE-ILLUSIE

BY KAZUYA KATO

1. Logarithmic structures.
2. Fine logarithmic structures.
4. Several types of morphisms.
5. Crystalline sites.

Complements.

Introduction. In this note, we present a general formulation of "logarithmic structure" on a scheme found by J. M. Fontaine and L. Illusie. Following their plan, we develop the theory of crystals with logarithmic poles using this logarithmic structure.

The logarithmic structure is "something" which gives rise to differentials with logarithmic poles, crystals and crystalline cohomology with logarithmic poles, . . . etc. For example, a reduced divisor with normal crossings on a regular scheme is such "something," and the logarithmic structure of Fontaine and Illusie is a natural generalization of this example to arbitrary schemes. Their logarithmic structure is defined to be a sheaf of commutative monoids \( M \) on the etale site \( X \) of a scheme \( X \), endowed with a homomorphism \( M \to \mathcal{O}_X \) satisfying a certain condition. (Cf. Section 1.) For \( X \) regular and \( D \) a reduced divisor with normal crossings on \( X \), the corresponding \( M \) is the sheaf of regular functions on \( X \) which are invertible outside \( D \). In general, the homomorphism \( M \to \mathcal{O}_X \) is not assumed to be injective.

Algebraic geometry works especially well with smooth morphisms. We can regard the theory of toroidal embeddings as a theory of varieties with smooth logarithmic structures over a field (cf. (3.7)). The logarithmic structure introduces a new range of smoothness, and we expect to have

Manuscript received November 8, 1988.
good algebraic geometry for smooth morphisms between logarithmic structures. In subsequent papers [HK], as was the motivation of Fontaine and Illusie, we apply our theory to schemes with semi-stable reduction, which are examples of schemes with smooth logarithmic structures over discrete valuation rings. (Cf. Complement 2 at the end of this note.)

I am very thankful to Fontaine and Illusie for the original definition of the logarithmic structure, their permission for me to develop their theory in this paper, advice and discussions. I was studying originally crystals with log. poles for regular schemes and reduced divisors with normal crossings, and I wished to write a note on log. str.'s of Fontaine-Illusie to know the best formulation of crystals with logarithmic poles.

Discussions between Illusie and M. Raynaud, and between Illusie and P. Deligne gave good influences to the theory.

The theory of logarithmic structures and crystals with logarithmic poles was developed independently by G. Faltings, and some parts of his papers [Fa, 1] [Fa, 2] overlap with our study. Our formulation is different from his (cf. Complement 1) and not covered by his theory. The theory of de Rham-Witt complex with logarithmic poles was considered by O. Hyodo [H, 1] [H, 2] and by M. Gros (unpublished). The theory of N. Katz [K] on connections with logarithmic poles was the guide for our theory.

I thank Université de Paris-Sud and Institut des Haute Etude Scientifique for the supports and hospitality during my study and writing.

1. Logarithmic structures. In this note, a monoid (resp. a ring) means a commutative monoid (resp. ring) with a unit element. A homomorphism of monoids (resp. rings) is required to preserve the unit elements.

For a monoid $M$, $M^\times$ denotes the associated group $\{ab^{-1}; a, b \in M\}$; $ab^{-1} = ca^{-1} = sad = sbc$ for some $s \in M$.

For a scheme $X$ and $x \in X$ and for a sheaf $\mathcal{F}$ on the etale site $X_{et}$, $\mathcal{F}_x$ denotes the stalk of $\mathcal{F}$ at the separable closure $\overline{x}$ of $x$. In particular, $\mathcal{O}_{X, \overline{x}}$ denotes the strict henselization of $\mathcal{O}_{X, x}$.

$(1.1)$. Pre-log. structures. Let $X$ be a scheme. A pre-logarithmic structure on $X$ is a sheaf of monoids $M$ on the etale site $X_{et}$ endowed with a homomorphism $\alpha : M \to \mathcal{O}_X$ with respect to the multiplication on $\mathcal{O}_X$.

A morphism $(X, M) \to (Y, N)$ of schemes with pre-log. str.'s is defined to be a pair $(f, h)$ of a morphism of schemes $f : X \to Y$ and a homomorphism $h : f^{-1}(N) \to M$ such that the diagram

is commutative.

$(1.2)$. is a logarithmic structure on $X$.

in the case of $\mathcal{O}_{X, \overline{x}}$.

Then, $M_{\overline{x}}$ is a logarithmic structure on $X_{\overline{x}}$.

$(R)$ for $\mathcal{O}_{X, \overline{x}}$.

there exist $\varepsilon, \eta, \xi \in \mathcal{O}_{X, \overline{x}}$ with $\varepsilon \eta = \xi$.

$(1.4)$. The morphism $\varepsilon \eta = \xi$ is called the identity of $X_{\overline{x}}$. 

LOGARITHMIC STRUCTURES

\[ f^{-1}(N) \rightarrow M \]
\[ \downarrow \]
\[ f^{-1}(\mathcal{O}_Y) \rightarrow \mathcal{O}_X \]

is commutative. (We use the notation \( f^{-1} \), not \( f^* \), for the inverse image of a sheaf, for we shall make a special use of the notation \( f^* \), cf. (1.4).)

(1.2). Log. structures. A pre-logarithmic structure \((M, \alpha)\) is called a logarithmic structure if

\[ \alpha^{-1}(\mathcal{O}_X^\times) \cong \mathcal{O}_X^\times \text{ via } \alpha \]

where \( \mathcal{O}_X^\times \) denotes the group of invertible elements of \( \mathcal{O}_X \). (We shall often identify \( \alpha^{-1}(\mathcal{O}_X^\times) \subset M \) with \( \mathcal{O}_X^\times \) via this isomorphism.) A morphism of schemes with log. str.'s is defined as a morphism of schemes with pre-log. str.'s.

(1.3). The log. str. associated to a pre-log. str. For a pre-log. str. \((M, \alpha)\) on \( X \), we define its associated log. str. \( M^\alpha \) to be the push out of

\[ \alpha^{-1}(\mathcal{O}_X^\times) \rightarrow M \]
\[ \downarrow \]
\[ \mathcal{O}_X^\times \]

in the category of sheaves of monoids on \( X_{et} \), endowed with

\[ M^\alpha \rightarrow \mathcal{O}_X; \quad (a, b) \mapsto \alpha(a)b \quad (a \in M, b \in \mathcal{O}_X^\times). \]

Then, \( M^\alpha \) is universal for homomorphisms of pre-log. str.'s from \( M \) to log. str.'s on \( X \).

(Remark. If \( G \twoheadrightarrow H \rightarrow M \) is a diagram of monoids with \( G \) a group, its push out is described as \((M \oplus G)/\sim \), where \((m, g) \sim (m', g') \) if there exist \( h_1, h_2 \in H \) such that \( mt(h_1) = m't(h_2), gs(h_2) = g's(h_1) \).)

(1.4). The direct image and the inverse image. Let \( f : X \rightarrow Y \) be a morphism of schemes. For a log. str. \( M \) on \( X \), we define the log. str. on \( Y \) called the direct image of \( M \), to be the fiber product of sheaves.
For a log. str. $M$ on $Y$, we define the log. str. on $X$ called the inverse image of $M$ and denoted by $f^*(M)$, to be the log. str. associated to the pre-log. str. $f^{-1}(M)$ endowed with the composite map $f^{-1}(M) \to f^{-1}(\mathcal{O}_Y) \to \mathcal{O}_X$. For a log. str. $M$ on $X$ and for a log. str. $N$ on $Y$, the following three sets are canonically identified: The set of homomorphisms from $N$ to the direct image of $M$, the set of homomorphisms from the inverse image of $N$ to $M$, and the set of extensions of $f$ to a morphism $(X, M) \to (Y, N)$.

The following facts concerning inverse images will be used frequently. Let $M$ be a log. str. on $Y$.

\begin{equation}
(1.4.1) \quad f^{-1}(M/\mathcal{O}_Y) \equiv (f^*M)/\mathcal{O}_X^N.
\end{equation}

\begin{equation}
(1.4.2) \quad \text{If $M$ is the log. str. associated to a pre-log. str. $M'$ on $Y$, $f^*(M)$ coincides with the log. str. associated to the pre-log. str. $f^{-1}(M') \to \mathcal{O}_X$.}
\end{equation}

\begin{equation}
(1.5) \quad \text{Examples of log. str.'s.} \quad (1) \quad \text{A standard example which we keep in mind is $(X, M)$ where $X$ is a regular scheme with a fixed reduced divisor $D$ with normal crossings, and $M$ is the log. str. on $X$ defined as}
\quad \quad \quad \quad \quad M = \{g \in \mathcal{O}_X; g \text{ is invertible outside } D\} \subset \mathcal{O}_X.
\end{equation}

The reason why we preferred the etale topology to the Zariski topology in this note is that the definition of "normal crossings" is etale local.

(2) For any scheme $X$, we call $M = \mathcal{O}_X^N \subset \mathcal{O}_X$ the trivial log. str. on $X$. This is the initial object in the category of log. str.'s on $X$. On the other hand, $M = \mathcal{O}_X$ is the final object in this category. The example (1.5)(1) is interpreted to be the direct image of the trivial log. str. on the open subscheme $X \to D$.

(3) Let $P$ be a monoid, $X$ a scheme, and assume we are given a homomorphism $P \to \Gamma(X, \mathcal{O}_X)$, or equivalently $P_X \to \mathcal{O}_X$ where $P_X$ denotes the constant sheaf on $X$ corresponding to $P$. Then, let $M$ be the log. str. associated to the pre-log. str. $P_X \to \mathcal{O}_X$. The log. str. of this type will play important roles in this paper. An interpretation of $M$ is the following. For
a ring, if $R[P]$ denotes the monoid ring on $P$ over $R$, $\text{Spec}(R[P])$ has a canonical log. str. associated to the canonical map $P \to R[P]$. The above log. str. $M$ on $X$ is the inverse image of the canonical log. str. on $\text{Spec}(\mathbb{Z}[P])$ under the morphism $X \to \text{Spec}(\mathbb{Z}[P])$. We mention what this $M$ is, under a certain assumption.

Claim. In the above, if $P$ has the property "$ab = ac \Rightarrow b = c$" and if $X$ is a scheme over a ring $R$ such that the induced morphism $X \to \text{Spec}(R[P])$ is flat, then $M$ is identified with the sub-monoid sheaf of $\mathcal{O}_X$ generated by $\mathcal{O}_X^P$ and $P$.

The proof of this claim will be given at the end of this section.

(1.6). Finite inverse limits. The category of schemes with log. str.'s has finite inverse limits. If $(X_\lambda, M_\lambda)$ is a finite inverse system, the inverse limit is $(X, M)$ where $X$ is the inverse limit of the system of schemes $X_\lambda$, and $M$ is obtained as follows. Let $p_\lambda : X \to X_\lambda$ be the projection, take the inductive limit $M'$ of the inductive system of sheaves of monoids $p^{-1}_\lambda(M_\lambda)$, and then let $M$ be the log. str. associated to the pre-log. str. $M' \to \mathcal{O}_X$.

(1.7). Logarithmic differentials. Let $\alpha : M \to \mathcal{O}_X$ and $\beta : N \to \mathcal{O}_Y$ be pre-log. str.'s, and let $f : (X, M) \to (Y, N)$ be a morphism. Then, we define the $\mathcal{O}_X$-module $\Omega^1_{X/Y}(\log(M/N))$, which is denoted simply by $\omega^1_{X/Y}$ for simplicity when there is no risk of confusion about the pre-log. str.'s, to be the quotient of

$$\Omega^1_{X/Y} \oplus (\mathcal{O}_X \otimes \mathbb{Z} M^\mathcal{O})$$

($\Omega^1_{X/Y}$ is the usual relative differential module) divided by the $\mathcal{O}_X$-submodule generated locally by local sections of the following forms.

(i) $(da(a), 0) - (0, \alpha(a) \otimes a)$ with $a \in M$.
(ii) $(0, 1 \otimes a)$ with $a \in \text{Image}(f^{-1}(N) \to M)$.

The class of $(0, 1 \otimes a)$ for $a \in M$ in $\omega^1_{X/Y}$ is denoted by $d \log(a)$.

It is easily seen that if $M^a$ and $N^a$ denote the associated log str.'s, respectively, we have

$$\Omega^1_{X/Y}(\log(M/N)) = \Omega^1_{X/Y}(\log(M^a/N^a)) = \Omega^1_{X/Y}(\log(M^a/N^a)).$$
If $M$ and $N$ are log. str.'s, we have a surjection

\[ \Theta_X \otimes_{\mathbb{Z}} M^{\text{ep}} \to \omega^1_{X/Y}; \quad a \otimes b \mapsto a.\log(b), \]

and the kernel is the $\Theta_X$-submodule generated locally by local sections of the forms

(i) $\alpha(a) \otimes a - \Sigma_i u_i \otimes u_i$ with $a \in M$ and $u_i \in \Theta_X^i$ such that $\alpha(a) = \Sigma_i u_i$,

(ii) $1 \otimes a$ with $a \in \text{Image}(f^{-1}(N) \to M)$.

If we have a cartesian diagram of schemes with log. str.'s

\[ (X', M') \xrightarrow{f} (X, M) \]
\[ \downarrow \quad \downarrow \]
\[ (Y', N') \to (Y, N), \]

we have an isomorphism

\[ f^*\omega^1_{X/Y} \cong \omega^1_{X'/Y'}. \]

(1.8). For example, let $P$ and $Q$ be monoids, $Q \to P$ a homomorphism, $R$ a ring, $X = \text{Spec}(R[P])$, $Y = \text{Spec}(R[Q])$, and endow $X$ and $Y$ with the canonical log. str.'s (1.5)(3), respectively. Then,

\[ \Theta_X \otimes_{\mathbb{Z}} (P^{\text{ep}}/\text{Image}(Q^{\text{ep}})) \cong \omega^1_{X/Y}; \quad a \otimes b \mapsto a.\log(b). \]

(1.9). In the situation (1.7), we define $\omega^1_{X/Y}$ to be the exterior algebra on the $\Theta_X$-module $\omega^1_{X/Y}$. It becomes a complex of $f^{-1}(\Theta_Y)$-modules in the natural way.

(1.10) Proof of the Claim in (1.5)(3). The problem is the injectivity of $M \to \Theta_X$. By the description of the push out in Remark in (1.3), it suffices to prove the following: If $x \in X$, $a, b \in P$ and $ab^{-1} \in \Theta_X^i$, then there exists $c, d \in P$ such that $c, d \in \Theta_X^i$ and $ac = bd$. (Note an element of $P$ is a nonzero-divisor on $X$ by the flatness assumption, and hence the expression $ab^{-1} \in \Theta_X^i$ makes sense.) Let $p$ be the image of $x$ in $\text{Spec}(R[P])$. Then, since $R[P]_p \to \Theta_X^i$ is faithfully flat, we have $ab^{-1} \in R[P]_p^i$. Hence $3f, g \in R[P]$ which are not contained in the prime ideal $p$ such that $af = bg$ in $R[P]$. Write $f = g + p$. Let $s \in P$ such that $p \not\subseteq s$. (2.1). A log. str. $\Theta_X$ is called coherent if the associated monoid $\Theta_X^i$ is isomorphic to $\mathbb{Z}$.

If $(X, \Theta_X)$ is a log. str.'s, $\Theta_X$ is called coherent if the associated monoid $\Theta_X^i$ is coherent and finitely generated $\Theta_X$-module.

(2.2). A log. str. $M$ is called coherent if the associated monoids.

(2.3). By our convention, $\text{Spec}$ is a fully faithful functor.

In this section, we adopt this convention.

(2.4).

(2.4.1). The spectrum of a ring, $\text{Spec}(R)$, is integral.

(2.4.2). A ring $R$ is called an algebra.

(2.4.3). A log. str. $(X, \Theta_X)$ is called finite if $\Theta_X^i$ is finitely generated.

Example: a log. str. $\Theta_X$, the coordinate ring of a variety $X$ over $\mathbb{C}$.
LOGARITHMIC STRUCTURES

197

\[ R[P]. \text{ Write } f = \Sigma_c f_c c, \ g = \Sigma_c g_c c, \text{ where } c \in P, f_c, g_c \in R. \text{ Take } c \in P \text{ such that } f_c, c \not\in \mathfrak{p}. \text{ Then, the equation } af = bg \text{ shows that there exists } d \in P \text{ such that } ac = bd. \text{ Since } c \not\in \mathfrak{p} \text{ and } ab^{-1} \in R[P]_r, \text{ we have } d \not\in \mathfrak{p}. \]

2. Fine log. structures.

(2.1) A log. str. \( M \) on a scheme \( X \) is called quasi-coherent (resp. coherent) if etale locally on \( X \), there exists a monoid (resp. finitely generated monoid) \( P \) and a homomorphism \( P_X \to \mathcal{O}_X \) whose associate log. str. is isomorphic to \( M \).

If \( (X, M) \to (Y, N) \) is a morphism of schemes with quasi-coherent log. str.'s, \( \omega^1_{X/Y} (1.7) \) is a quasi-coherent \( \mathcal{O}_X \)-module. If furthermore \( M \) is coherent and \( X \) is noetherian and locally of finite type over \( Y \), it is a coherent \( \mathcal{O}_X \)-module.

(2.2) A monoid is called integral if \( \text{"} ab = ac = b = c \text{"} \) holds. A log. str. \( M \) on a scheme \( X \) is called integral if \( M \) is a sheaf of integral monoids.

(2.3) We call a log. str. "fine" if it is coherent and integral.

In this note, we consider mainly fine logarithmic structures. (To my experience, nonintegral log. str.'s are too much pathological.)

(2.4) The following facts are proved easily.

(2.4.1) If \( f: X \to Y \) is a morphism and \( M \) is a quasi-coherent (resp. coherent, resp. integral) log. str. on \( Y \), so is \( f^*(M) \).

(2.4.2) A quasi-coherent (resp. coherent) log. str. \( M \) on a scheme \( X \) is integral if and only if etale locally on \( X \), \( M \) is isomorphic to the log. str. associated to the pre-log. str. \( P_X \to \mathcal{O}_X \) for some integral (resp. finitely generated integral) monoid \( P \).

(2.4.3) If \( M \) is coherent (resp. integral), the stalk \( M_x/\mathcal{O}^+_x \) is a finitely generated (resp. integral) monoid for any \( x \in X \).

Example (2.5). (1) The log. str. on a regular scheme \( X \) corresponding to a reduced divisor with normal crossings (1.5)(1) is fine. Indeed, etale
locally on \( X \), write \( D = \bigcup_i \pi_i = 0 \) where \( \pi_i = 0 \) are regular closed subschemes of \( X \). Then, \( M \) is associated to the pre-log. str.

\[
N' \to \mathcal{O}_X; \quad (n_i)_{1 \leq i \leq r} \mapsto \prod_i \pi_i^{n_i}
\]

and the monoid \( N' \) is clearly finitely generated and integral.

(2) If \( X = \text{Spec}(k) \) for an algebraically closed field \( k \), there is a bijection between the two sets

\{ isomorphism classes of integral log. str.'s on \( X \) \}

\{ isomorphism classes of integral monoids having no invertible element other than the unit element \}

given in the following way. For an integral monoid \( P \) as above, the corresponding log. str. is \( M = \mathcal{O}_X^\times \oplus P \) with

\[
M \to \mathcal{O}_X; \quad (a, b) \mapsto a \quad (\text{resp. } 0) \quad \text{if } b = 1 \quad (\text{resp. } b \neq 1).
\]

**Proposition (2.6).** The inverse limit of a finite inverse system of schemes with log. str.'s (1.6) is coherent if each member of the system is coherent.

**Proof.** It is enough to consider finite direct products and equalizers. By the description of finite inverse limits in (1.6), the case of finite direct products is clear, and for equalizers, it is enough to prove the following. Assume we are given two homomorphisms \( g, h : M \to N \) of log. str.'s on \( X \), let \( L' \) be the co-equalizer of \( (g, h) \) in the category of sheaves of monoids, and let \( L \) be the log. str. associated to \( L' \). Then, if \( M, N \) are coherent, \( L \) is coherent. To see this, take finitely generated monoids \( P, Q \) and homomorphisms \( s : P \to M, t : Q \to N \) which induce \((P_X)^\oplus \equiv M, (Q_X)^\oplus \equiv N \). If we have homomorphisms \( g', h' : P \to Q \) compatible with \( g \) and \( h \), respectively, then \( L \) is associated to the coequalizer of \((g', h') \) in the category of monoids (which is endowed with the induced homomorphism to \( \mathcal{O}_X \)), and hence is coherent. In general we may not have such \((g', h') \), but considering the commutative diagram

\[
\begin{array}{ccc}
P & \xrightarrow{i_1} & Q' = P \oplus P \oplus Q \\
\downarrow & & \downarrow \scriptscriptstyle t'=(g,h,t) \\
M & \xrightarrow{g} & N
\end{array}
\]

\((i_1(x) = (x, x, 0), \text{etale locally})\)

\(Q' \to Q'' \to \cdots \) generated by \( u_i \in \mathcal{O}_{X,x}^\times \). Let \( M \) be generated by \( u_i \) a base of \( N' \). Consider \( M \) by \( e_i \mapsto (Q_i)^a \to (Q_i) \),

**Proposition (2.6).** The inverse limit of a finite inverse system of schemes with log. str.'s has a real.

**Proof.**

As constructs \( (X', \mathcal{O}'_X) \), isomorphisms from \( (\mathcal{O}'_X)^\times \) and hence an

\[
\text{where } P_{\text{str'}} = \text{by } X' \to \text{Spec } k.
\]

We shall have

(2.8).

str.'s and \( (X', \mathcal{O}'_X) \) in the log. str.'s, \( (\mathcal{O}'_X)^\times \). In schemes with log. str.'s, schemes with log. str.'s, schemes with log. str.'s, etc.) as the category of schemes.

**Definition.**

If \( M \) is a homomorphism \( P \) which induces

integrals.

lemmas, there is a bijec-

tion for N.

If a, b are invertible ele-

ments and a divides b (resp. \( b \neq 1 \)).

Every object is an inverse system of objects of the system is the inverse system of objects and equalizers.

In the case of finite direct limits we have the following.

If \( (X, M) \) is a scheme of log. str.'s on \( X \), then (i) each sheaf of monoids on \( X \) is a sheaf of \( Q \) and homomorphism \( \phi : (Q_x) \rightarrow (M_x) \) is a morphism of sheaves of monoids, \( (Q_x) \equiv N \). If \( \phi_i \) is an isomorphism for \( i \), \( \phi \) is an isomorphism. We have \( (Q_x) \equiv N \) in the category of schemes with fine log. str.'s. In the category of schemes with fine log. str.'s, various properties of morphisms between schemes with fine log. str.'s defined in later sections (smoothness, etaleness, etc.) are preserved by base changes using the fiber products in the category of schemes with fine log. str.'s.

**Definition (2.9).**

1. For a scheme \( X \) with a fine log. str. \( M \), a chart of \( M \) is a homomorphism \( P_X \rightarrow M \) for a finitely generated integral monoid \( P \) which induces \( (P_X)_x \equiv M \).

A chart of \( M \) exists etale locally.

2. For a morphism \( f : (X, M) \rightarrow (Y, N) \) of schemes with fine log. str.'s, a chart of \( f \) is a triple \( (P_X \rightarrow M, Q_Y \rightarrow N, Q \rightarrow P) \) where \( P_X \rightarrow M \),
$Q_Y \to N$ are charts of $M$ and $N$, respectively, and $Q \to P$ is a homomorphism for which

$$
\begin{array}{ccc}
Q_X & \longrightarrow & P_X \\
\downarrow & & \downarrow \\
 f^{-1}(N) & \longrightarrow & M
\end{array}
$$

is commutative.

A chart of $f$ also exists étale locally. This fact is deduced easily from

**Lemma (2.10).** Let $X$ be a scheme with a fine log. str. $M$, let $x \in X$, $G$ a finitely generated abelian group, and let $h : G \to M^\text{gp}_x$ be a homomorphism such that $G \to M^\text{gp}_x/\mathcal{O}_X^\times_x$ is surjective. Let $P = (h^\text{gp})^{-1}(M_x)$. Then, $P \to M_x$ is extended to a chart $P_U \to M|_U$ for an étale neighbourhood $U$ of $x$.

**Proof.** First, $P$ is finitely generated since

$$(*) \quad P/(\text{a subgroup}) \cong M_x/\mathcal{O}_X^\times_x$$

and $M_x/\mathcal{O}_X^\times_x$ is finitely generated. When we extend $P \to M_x$ to a homomorphism $P_U \to M|_U$ for an étale neighbourhood $U$ of $x$, $(*)$ proves $((P_U)^a)_x \cong M_x$. This shows that $(P_U)^a \cong M|_U$ for an étale neighbourhood $U'$ of $x \to U$.

### 3. Smooth morphisms.

**(3.1).** We call a morphism of schemes with log. str.'s $i : (X, M) \to (Y, N)$ a closed immersion (resp. an exact closed immersion) if the underlying morphism of schemes $X \to Y$ is a closed immersion and $i^*N \to M$ is surjective (resp. an isomorphism).

**(3.2).** We shall often consider a commutative diagram of schemes with fine log. str.'s

$$
\begin{array}{ccc}
(T', L') & \longrightarrow & (X, M) \\
\downarrow & & \downarrow \\
(T, L) & \longrightarrow & (Y, N)
\end{array}
$$

such that $i$ is étale and $j$ is the ideal $I$ such that $i(I) = 0$.

**Remark (3.3).** Such a morphism of schemes will be called a finite étale morphism. Consider a commutative diagram as above and let $g$ be a unique) $g : (T', L') \to (Y, N)$.

A standard argument shows that the following lemma shall see that the form of this standard argument.

**Proposition (3.4).** Let $i : (X, M) \to (Y, N)$ be the same étale morphism as in the previous paragraph. Then, the morphism $i^*: \	ext{log torsion part of } N \to M$ is finite étale.

**Proof.** First, we will embed $I$ in $\mathcal{O}_Y^\times$.

By the assumption, we have a commutative diagram

$$
\begin{array}{ccc}
(T', L') & \longrightarrow & (X, M) \\
\downarrow & & \downarrow \\
(T, L) & \longrightarrow & (Y, N)
\end{array}
$$

and endow $\mathcal{O}_Y^\times$ with a $\mathcal{O}_X^\times$-module structure.

Then, the morphism $i^*: \text{log torsion part of } N \to M$ is finite étale.
such that \( i \) is an exact closed immersion (3.1) and \( T' \) is defined in \( T \) by an ideal \( I \) such that \( I^2 = (0) \).

(3.3). Smoothness and etaleness. A morphism \( f : (X, M) \to (Y, N) \) of schemes with fine log. str.'s is called smooth (resp. etale) if the underlying morphism \( X \to Y \) is locally of finite presentation and if for any commutative diagram as in (3.2), there exists etale locally on \( T \) (resp. there exists a unique) \( g : (T, L) \to (X, M) \) such that \( gi = s \) and \( fg = t \).

A standard example of a smooth (resp. etale) morphism is given by the following (3.4). In (3.5), which is the main result of this section, we shall see that all smooth (resp. etale) morphisms are essentially of the type of this standard example.

**Proposition (3.4).** Let \( P, Q \) be finitely generated integral monoids, \( Q \to P \) a homomorphism, \( R \) a ring, such that the kernel and the torsion part of the cokernel (resp. the kernel and the cokernel) of \( Q^{\text{gp}} \to P^{\text{gp}} \) are finite groups whose orders are invertible in \( R \). Let

\[
X = \text{Spec}(R[P]), \quad Y = \text{Spec}(R[Q])
\]

and endow them with the canonical log. str.'s \( M \) and \( N \), respectively. Then, the morphism \((X, M) \to (Y, N)\) is smooth (resp. etale).

**Proof.** Consider a commutative diagram as in (3.2). Then, if we embed \( I \) in \( L \) via the injective homomorphism

\[
I \to \mathcal{O}_L^+ \subseteq L; \quad x \mapsto 1 + x,
\]

we have a cartesian diagram

\[
\begin{array}{ccc}
L & \longrightarrow & L/I = L' \\
\downarrow & & \downarrow \\
L^{\text{gp}} & \longrightarrow & (L')^{\text{gp}} \\
\end{array}
\]

(3.4.1)

By the assumption on \( Q^{\text{gp}} \to P^{\text{gp}} \), we have the following dotted arrow etale locally (resp. uniquely) which makes the diagram commutative;

\[
(L')^{\text{gp}} \quad \longrightarrow \quad P^{\text{gp}} \\
\uparrow \\
L^{\text{gp}} \quad \quad Q^{\text{gp}}.
\]
By the cartesian diagram (3.4.1), we obtain \( P \to L \) which induces the desired morphism \( (T, L) \to (X, M) \).

**Theorem (3.5).** Let \( f : (X, M) \to (Y, N) \) be a morphism of schemes with fine log. str.'s. Assume we are given a chart (2.9) \( Q_Y \to N \) of \( N \). Then the following conditions (3.5.1) and (3.5.2) are equivalent.

(3.5.1). \( f \) is smooth (resp. etale).

(3.5.2). Etale locally on \( X \), there exists a chart \( (P_X \to M, Q_Y \to N, Q \to P) \) of \( f \) extending the given \( Q_Y \to N \) satisfying the following conditions (i)(ii).

(i) The kernel and the torsion part of the cokernel (resp. The kernel and the cokernel) of \( Q^{et} \to P^{et} \) are finite groups of orders invertible on \( X \).

(ii) The induced morphism from \( X \to Y \times_{\text{Spec}(\mathbb{Z}(P))} \text{Spec}(\mathbb{Z}(P)) \) is etale (in the classical sense).

**Remark (3.6).** The proof of (3.5) will show the following facts. We can require in the condition (3.5.2)(i) that \( Q^{et} \to P^{et} \) is injective, without changing the conclusion of (3.5). In the part concerning the smoothness of \( f \), we can replace the etaleness of the morphism from \( X \) to the fiber product in (3.5.2), by the smoothness (also in the classical sense), without changing the conclusion of (3.5).

**Examples (3.7).** (1) Let \( k \) be a field and let \( X \) be a scheme over \( k \) locally of finite type with a fine log. str. \( M \). Then, by (3.5), \( (X, M) \) is smooth over \( \text{Spec}(k) \) if and only if etale locally on \( X \), there exists a finitely generated integral monoid \( P \) and an etale morphism \( X \to \text{Spec}(k[P]) \) satisfying the following conditions; \( M = P^{et} \subset \mathcal{O}_X \), the torsion part of \( P^{et} \) is of order invertible in \( k \). Thus \( (X, M) \) corresponds to a toroidal embedding [KKMS] which is locally given by the open immersion

\[
X \times_{\text{Spec}(k[P])} \text{Spec}(k[P^{et}]) \subset X.
\]

We assume \( P^{et} \) is torsion free in the usual theory of toroidal embeddings, but essentially, the theory of toroidal embeddings is nothing but the theory of schemes with smooth fine log. str.'s over a field (with respect to the trivial log. str. on the base field).

(2) Let \( A \) be a discrete valuation ring, \( X \) a regular scheme over \( A \) such that etale locally on \( X \), there is a smooth morphism \( X \to \text{Spec}(A[T_1, \ldots, T_n]) \) and \( A \)-rational points of \( X \). (In the proof of (3.5.2)(ii), we assume \( M \) (resp. the special fiber of \( X \)) is a finitely generated free \( A \)-module and \( (X, M) \to (X, M') \) is étale for some \( M' \).

For the statement of (3.5.2)(i), we choose \( P \) and \( P^{et} \) on \( X \) as in (3.5.2)(ii).

**Proposition (3.8).** Suppose \( f : (X, M) \to (Y, N) \) is a morphism of schemes with fine log. str.'s (resp. étale) if and only if \( f \) is smooth (resp. étale).

**Proof.**

**Proof of (3.8).**

The proof is a direct verification of (3.5).

**Proposition (3.9).** Suppose \( f : (X, M) \to (Y, N) \) is a morphism of schemes with fine log. str.'s. Then, for any \( A \)-rational point \( x \) of \( X \), we have

\[
h(x) = \frac{u(x)}{v(x)},
\]

where \( u(a) \to v(a) \) is a nonzero rational function on \( X \) with \( a = f(x) \).

**Proof.**

The proof is a direct verification of (3.5).

**Corollary (3.10).** Suppose \( f : (X, M) \to (Y, N) \) is a morphism of schemes with fine log. str.'s. Then, for any \( A \)-rational point \( x \) of \( X \), we have

\[
h(x) = \frac{u(x)}{v(x)}
\]

where \( u(a) \to v(a) \) is a nonzero rational function on \( X \) with \( a = f(x) \).

**Proof.**

The proof is a direct verification of (3.5).
induces the descent of the log. str. on $X$ to $N$ of $N$. Then

$$
\text{Hom}_X(M, Q) \to N, \quad \text{then }
$$

$$
\text{Hom}_X(M, Q) \to N,
$$

the following facts. We esp. The kernel of the above morphisms is $O(Y)^*$ invertible on $X$. Thus $O(Y)^* \to O$, Spec($\mathbb{Z}[P])$ is smooth.

The following facts. We have proved (3.7) and (3.8). The smoothness of $O(Y)^*$ over $Y$ implies the smoothness of $O(Y)^*$ over $Y$.

For the proof of (3.5), we use the following facts.

\textbf{Proposition (3.8).} Let $f : (X, M) \to (Y, N)$ be a morphism of schemes with fine log. str.'s such that $f^* N \cong M$. Then $f$ is smooth (resp. etale) if and only if the underlying morphism $X \to Y$ is smooth (resp. etale).

\textit{Proof.} Exercise.

\textbf{Proposition (3.9).} In (3.2), assume we are given one morphism $g : (T, L) \to (X, M)$ such that $g_1 = s$ and $g_2 = t$. Then there exists a bijection

$$
\{h : (T, L) \to (X, M); hi = s, fh = t\} \to \text{Hom}_{X^T}(s^* \omega^*_{X/Y}, I)
$$

which sends $h$ to the homomorphism

$$
da \to h^*(a) - g^*(a) \quad \text{for } a \in O_X,
$$

$$
d \log(a) \to u(a) - 1 \quad \text{for } a \in M,
$$

where $u(a)$ is the unique local section of $\text{Ker}(O_X^* \to O_Y^*) \subset L$ such that $h^*(a) = g^*(a) u(a)$.

\textit{Proof.} Exercise.

The proofs of the following (3.10) (3.12) are reduced to (3.9) in the same way as in the theory of the classical smoothness.

\textbf{Proposition (3.10).} Let $f : (X, M) \to (Y, N)$ be a smooth morphism of schemes with fine log. str.'s. Then the $O_X$-module $\omega^*_{X/Y}$ is locally free of finite type.

\textbf{Corollary (3.11).} If $f : (X, M) \to (Y, N)$ is smooth in the diagram (3.2), a morphism $g : (T, L) \to (X, M)$ such that $g_1 = s$ and $g_2 = t$ exists whenever $T$ is affine.

Indeed, the obstruction to glueing local $g$ lies in $H^1(T', \text{Hom}_{O_T}(s^* \omega^*_{X/Y}, I)) = (0)$. 

\textbf{Logarithmic Structures}

203

Spec($\mathbb{A}[T_1, \ldots, T_r]/(T_1 \cdots T_r - \pi)$) for $r \geq 1$ and a prime element $\pi$ of $A$. (In this situation, $X$ is called of semi-stable reduction over $A$.) Then, if $M$ (resp. $N$) denotes the log. str. on $X$ (resp. Spec($A$)) corresponding to the special fiber of $X$ (resp. the closed point of Spec($A$)), which is a reduced divisor with normal crossings on a regular scheme, the morphism $(X, M) \to \text{Spec}(A, N)$ is smooth.
Proposition (3.12). Let \((X, M) \xrightarrow{f} (Y, N) \xrightarrow{s} (S, L)\) be morphisms of schemes with fine log. str.'s, and let

\[ f^*\omega_{X/S} \xrightarrow{s} \omega_{Y/S} \rightarrow \omega_{X/Y} \rightarrow 0 \]

be the associated exact sequence. Consider the following conditions.

(i) \(f\) is smooth (resp. etale).

(ii) \(s\) is injective and the image of \(s\) is locally a direct summand (resp. \(s\) is an isomorphism).

Then, we have the implication (i) \(\Rightarrow\) (ii). If \(gf\) is smooth, we have (ii) \(\Rightarrow\) (i).

(3.13). Proof of (3.5). The implication (3.5.2) \(\Rightarrow\) (3.5.1) follows from (3.4) (3.8).

We prove the converse. We construct \(P\) etale locally as follows.

Fix \(x \in X\). Take elements \(t_1, \ldots, t_n\) of \(M_x\) such that \((d \log(t_i))_{i \in \mathbb{Z}}\) is a basis of \(\omega_{X/Y, x}\) (3.10). Consider

\[ N^r \oplus Q \rightarrow M_x \]

induced by \(N^r \rightarrow M_x\); \((m_i) \rightarrow \Pi_i t_i^{m_i}\) and by \(Q \rightarrow f^{-1}(N)\) \(\rightarrow M_x\). Note \(M_x/\Theta_{X,x}^q\) is finitely generated. The map

\[ \omega_{X/Y, x} \rightarrow \kappa(x) \otimes \mathbb{Z} (M_x^q/(\Theta_{X,x}^q \text{ Image}(f^{-1}(N)_{x}^q))) \]

\[ d \log(a) \mapsto 1 \otimes a \quad (a \in M_x) \]

shows that

\[ \kappa(x) \otimes \mathbb{Z} (Z' \oplus Q^p) \rightarrow \kappa(x) \otimes \mathbb{Z} (M_x^p/\Theta_{X,x}^p) \]

is surjective, and hence the cokernel of

\[ Z' \oplus Q^p \rightarrow M_x^p/\Theta_{X,x}^p \]

generated at \(x\) is annihilated by \(n\) for some \(n\). By using the fact that \(\Theta_{X,x}^p\) is \(n\)-divisible, we can easily construct a finitely generated \(n\)-module \(Q^p \rightarrow P^p \rightarrow M^p\) which is generated at \(x\) by \(n\).

By (3.10), by replacing the base scheme \(X\) by \(\nu\),

\[(*)\]

Furthermore, if \(g\) is etale then \(g\) is smooth. With the canonical log structure \(M_{\nu}^p\) on \(M\), it is sufficient to prove that \(g\) is smooth. This follows from (3.8).

The third part of (3.5) then follows from (3.10).

Proposition (3.14). Let \(g: (\tilde{Y}, \tilde{N}) \rightarrow (Y, N)\) be a \(\Theta\)-morphism which is etale at \(x \in X\). Then \((\tilde{X}, \tilde{M}) \rightarrow (X, M, f_{\tilde{x}})\) is etale at \(\tilde{x} \in \tilde{X}\) defined in \(\tilde{Y}\).

(1) If \(\kappa(x)/\kappa(\tilde{x})\) is an extension up to isomorphism of finitely generated \(\Theta\)-modules, \(X\) is a scheme.

(2) Assume \(\kappa(x)/\kappa(\tilde{x})=\Theta_{X,x}/\Theta_{\tilde{X},\tilde{x}, \tilde{x}}\) is an extension up to isomorphism of finitely generated \(\Theta\)-modules.

(3) Assume \(\kappa(x)/\kappa(\tilde{x})\) is an extension up to isomorphism of finitely generated \(\Theta\)-modules.

(4) Assume \(\kappa(x)/\kappa(\tilde{x})\) is an extension up to isomorphism of finitely generated \(\Theta\)-modules.

(5) Assume \(\kappa(x)/\kappa(\tilde{x})\) is an extension up to isomorphism of finitely generated \(\Theta\)-modules.

(6) Assume \(\kappa(x)/\kappa(\tilde{x})\) is an extension up to isomorphism of finitely generated \(\Theta\)-modules.

(7) Assume \(\kappa(x)/\kappa(\tilde{x})\) is an extension up to isomorphism of finitely generated \(\Theta\)-modules.

(8) Assume \(\kappa(x)/\kappa(\tilde{x})\) is an extension up to isomorphism of finitely generated \(\Theta\)-modules.

(9) Assume \(\kappa(x)/\kappa(\tilde{x})\) is an extension up to isomorphism of finitely generated \(\Theta\)-modules.

(10) Assume \(\kappa(x)/\kappa(\tilde{x})\) is an extension up to isomorphism of finitely generated \(\Theta\)-modules.
Let \( f : (X, M) \to (Y, N) \) be a smooth morphism between schemes with fine log. str.'s, and let \( i : (Y, N) \to (\tilde{Y}, \tilde{N}) \) with \( N \) fine be an exact closed immersion (3.2) such that \( Y \) is defined in \( \tilde{Y} \) by a nilpotent ideal \( I \) of \( O_{\tilde{Y}} \). Then we have:

1. If \( X \) is affine, a smooth lifting of \((X, M, f)\) exists and is unique up to isomorphism. Here, by a smooth lifting of \((X, M, f)\), we mean a scheme \( \tilde{X} \) with a fine log. str. \( \tilde{M} \) endowed with a smooth morphism \( \tilde{f} : (\tilde{X}, \tilde{M}) \to (\tilde{Y}, \tilde{N}) \) and with an isomorphism

\[
g : (X, M) \cong (\tilde{X}, \tilde{M}) \times (\tilde{Y}, \tilde{N}) (Y, N) \text{ over } (Y, N).
\]

2. Assume \( I^2 = (0) \). Then, for a smooth lifting \((\tilde{X}, \tilde{M}, \tilde{f}, g)\) of \((X, M, f)\), there exists a canonical isomorphism

\[
\text{Aut}(\tilde{X}, \tilde{M}, \tilde{f}, g) = \text{Hom}_O(\omega_{\tilde{X}/\tilde{Y}}, I\Theta_{\tilde{X}}).
\]
(3) Assume $I^2 = (0)$. If we are given one fixed smooth lifting of $(X, M, f)$, we have a bijection from the set of all isomorphism classes of smooth liftings of $(X, M, f)$ to

$$H^1(X, \mathcal{O}_X(\omega_{X/Y}, I\mathcal{O}_X)).$$

(4) A smooth lifting of $(X, M, f)$ exists if $I^2 = (0)$ and if

$$H^2(X, \mathcal{O}_X(\omega_{X/Y}, I\mathcal{O}_X)) = (0).$$

Proof. Once we prove that a smooth lifting exists etale locally on $X$, the statements in (3.14) are deduced from it by the classical arguments as in SGA I Exposé 3. Etale locally we have a chart $(P_x \to M, Q_x \to N, Q \to P)$ of $f$ satisfying the condition (3.5.2) such that $Q_y \to N$ factors through a chart $Q_y \to \tilde{N}$ of $\tilde{N}$. Let

$$X' = Y \times_{\text{Spec}(\mathbb{Z}(p))} \text{Spec}(\mathbb{Z}[P]), \quad \tilde{X}' = \tilde{Y} \times_{\text{Spec}(\mathbb{Z}(p))} \text{Spec}(\mathbb{Z}[P]).$$

Lift the etale scheme $X$ over $X'$ to an etale scheme $\tilde{X}$ over $\tilde{X}'$ (this is classical; SGA I Exposé 1), and endow $\tilde{X}$ with the inverse image $\tilde{M}$ of the canonical log. str. on $\text{Spec}(\mathbb{Z}[P])$. Then, $(\tilde{X}, \tilde{M}, \tilde{f}, g)$ with the evident definitions of $\tilde{f}, g$ is a smooth lifting.

4. Several types of morphisms. We define integral morphisms (4.3), exact morphisms (4.6), and morphisms of Cartier type (4.8), describe their properties, and prove a Cartier isomorphism (4.12).

Proposition (4.1). (1) Let $h : Q \to P$ be a homomorphism of integral monoids. Then, the following conditions (i) and (iv) are equivalent (resp. (ii), (iii) and (v) are equivalent).

(i) For any integral monoid $Q'$ and for any homomorphism $g : Q \to Q'$, the push out of $P \leftarrow Q \to Q'$ in the category of monoids is integral.

(ii) The homomorphism $\mathbb{Z}(Q) \to \mathbb{Z}[P]$ induced by $h$ is flat.

(iii) For any field $k$, the homomorphism $k[Q] \to k[P]$ induced by $h$ is flat.

(iv) If $a_1, a_2 \in Q, b_1, b_2 \in P$ and $h(a_1)b_1 = h(a_2)b_2$, there exist $a_3, a_4 \in Q$ and $b \in P$ such that $b_1 = h(a_3)b, b_2 = h(a_4)b$, and $a_1a_3 = a_2a_4$.

(v) The condition (iv) is satisfied and $h$ is injective.
(2) Let \( f : (X, M) \to (Y, N) \) be a morphism of schemes with integral log. str. Then, for \( x \in X \), the conditions (i)-(v) in (1) for \( Q = f^*N \) and \( P = M \) are equivalent, and they are equivalent to each of (i)-(v) for \( Q = f^{-1}(N/\mathcal{O}_X^\times) \) and \( P = (M/\mathcal{O}_X^\times) \).

\[ \text{(4.2). Proof of (4.1).} \]

(1) We omit the proof of (4.1)(2) since it is easy by considering the conditions (4.1)(iv) and (v).

(i) \( = \) (iv). Let \( a_1, a_2 \in Q, b_1, b_2 \in P \) and \( h(a_1)b_1 = h(a_2)b_2 \). Define \( Q' = (Q \otimes \mathbb{N}^2)/\sim \), where \( \sim \) is the equivalence relation

\[ (c, m, n) \sim (c', m', n') \iff m + n = m' + n' \quad \text{and} \quad ca_1^m a_2^n = c'a_1^{m'} a_2^{n'} , \]

and let \( P' \) be the push out of \( P \leftarrow Q \to Q' \). Since \( Q' \) is integral and (i) is satisfied, \( P' \) is also integral and we see from this that \( (b_1, 1, 0) \) and \( (b_2, 0, 1) \) coincide in \( P' \). It follows that there exists a sequence \( v_0, \ldots, v_r \) of elements of \( P \otimes \mathbb{N}^2 \) such that \( v_0 = (b_1, 1, 0), v_r = (b_2, 0, 1) \) and such that for each \( i = 1, \ldots, r \), there exist \( c, c' \in Q, m, n, m', n' \in \mathbb{N} \) and \( w \in P \otimes \mathbb{N}^2 \) satisfying \( v_{i-1} = (h(c), m, n)w, v_i = (h(c'), m', n')w, m + n = m' + n', ca_1^m a_2^n = c'a_1^{m'} a_2^{n'} \). As is easily seen, this implies that there exist \( a_3, a_4 \in Q \) and \( b \in P \) such that \( b_1 = h(a_3)b, b_2 = h(a_4)b, a_1a_3 = a_2a_4 \).

(iv) \( \Rightarrow \) (i). Let \( P' \) be the push out. We prove the surjection \( P' \to (P')^{\text{inv}} \) is injective. Let \( b_1, b_2 \in P, c_1, c_2 \in Q \) and assume \( b_1c_1 = b_2c_2 \). Then, an easy observation on the push out of \( P^{\text{op}} \leftarrow Q^{\text{op}} \to (Q')^{\text{op}} \) shows that there exist \( a_1, a_2 \in Q \) such that \( h(a_1)b_1 = h(a_2)b_2 \) in \( P \) and \( g(a_1)c_1 = g(a_2)c_2 \) in \( Q' \). By the condition (iv), we have \( b_1 = h(a_3)b, b_2 = h(a_4)b, a_1a_3 = a_2a_4 \). We have \( g(a_1)c_1 = g(a_4)c_2 \) in \( Q' \), and hence we have in \( P' \) (not only in \( P'^{\text{inv}} \))

\[ b_1c_1 = b_1(h(a_3)b)c_1 = b(h(a_4)b)c_2 = (h(a_4)b)c_2 = b_2c_2. \]

(iii) \( \Rightarrow \) (v). We show first \( h \) is injective. Let \( a_1, a_2 \in Q \) and let \( k \) be any field. As is easily seen, the kernel of the multiplication by \( a_1 - a_2 \) on \( k[Q] \) is generated, as an ideal, by elements of the form \( \sum_{i=1}^{n} c_i \) (\( n \geq 1, c_i \in Q \)) such that \( a_1c_i = a_2c_{i+1} \) for \( i = 1, \ldots, n-1 \) and \( a_1^n = a_2^n \). By the
flatness of $k[Q] \to k[P]$, the images of these elements in $k[P]$ generates as an ideal, the kernel of the multiplication by $h(a_1) - h(a_2)$ on $k[P]$. If $h(a_1) = h(a_2)$, the above elements satisfy $h(c_i) = \cdots = h(c_n)$ and hence $k[P]$ is generated as an ideal by the elements $h(\sum_{1 \leq i \leq r} c_i) = nh(c_1)$. Hence $n$ is invertible in any field $k$ and hence $n = 1$, that is, $a_1 = a_2$.

Next assume $h(a_1)b_1 = h(a_2)b_2$, $a_1, a_2 \in Q$ and $b_1, b_2 \in P$. Let $S$ be the kernel of

$$k[Q] \oplus k[Q] \to k[Q]; \quad (f, g) \mapsto a_1g - a_2f.$$ 

By the flatness, the kernel $T$ of

$$k[P] \oplus k[P] \to k[P]; \quad (f, g) \mapsto h(a_1)g - h(a_2)f$$

is generated as a $k[P]$-module, by the image of $S$. Since $(b_1, b_2) \in T$, we can write

$$b_1 = \sum_{1 \leq i \leq r} h(c_i)f_i, \quad b_2 = \sum_{1 \leq i \leq r} h(d_i)f_i, \quad a_1c_i = a_2d_i$$

for some $c_i, d_i \in k[Q], f_i \in k[P]$ $(1 \leq i \leq r)$. The expression of $b_1$ in (*) shows that there are $a_3 \in Q$ and $b \in P$ and $i$ such that $a_3$ appears in $c_i$, $b$ appears in $f_i$, and $b_1 = h(a_3)b$. By $a_1c_i = a_2d_i$, there exist $a_4 \in Q$ which appear in $d_i$ such that $a_1a_3 = a_2a_4$. We have $b_2 = h(a_4)b$ by

$$h(a_2)b_2 = h(a_1)b_1 = h(a_1a_3)b = h(a_2)a_4b.$$

**Definition (4.3).** Let $f: (X, M) \to (Y, N)$ be a morphism of schemes with integral log. str.'s. We say $f$ is integral if for any $x \in X$, the equivalent conditions in (4.1)(2) are satisfied.

That $f$ is integral (Resp. In the case $M$ and $N$ are fine, that $f$ is integral) is equivalent to the following .

(4.3.1). For any scheme $Y'$ with an integral (resp. a fine) log. str. $N'$ and for any $(Y', N') \to (Y, N)$, the log. str. of the fiber product $(X, M) \times_{(Y, N)} (Y', N')$ is integral.
The implication "(4.1)(i) for $Q = (f^*N)_x$ and $P = M_x$ holds for any $x \in X \Rightarrow (4.3.1)"$ is proved easily. The implication "(4.3.1) = (4.1)(iv) for $Q = (f^*N)_x$ and $P = M_x$ holds for any $x \in X$" is proved by the method of the proof of (iv) = (i) given in (4.2).

**Corollary (4.4).** A morphism $f : (X, M) \to (Y, N)$ of schemes with integral log. str.'s is integral in each of the following cases:

(i) $M$ is isomorphic to the inverse image of $N$.

(ii) For any $y \in Y$, the monoid $(N/\mathfrak{m}_y^c)_{\mathfrak{m}_y}$ is generated by one element.

**Proof.** For the case (ii), consider the condition (iv) in (4.1)(i).

For example, the morphism $(X, M) \to (\text{Spec}(A), N)$ in (3.7)(2) (the semi-stable reduction situation) is integral.

**Corollary (4.5).** If a morphism $f$ of schemes with fine log. str.'s is smooth and integral, the underlying morphism $X \to Y$ is flat.

**Proof.** By using (ii) of (4.1)(i), we can find etale locally a chart $(P_X \to M, Q_Y \to N, Q \to P)$ satisfying (3.5.2) such that $\mathbb{Z}[Q] \to \mathbb{Z}[P]$ is flat.

**Definition (4.6).** (1) We say a homomorphism of integral monoids $h : Q \to P$ is exact if $Q = (h^p)^{-1}(P)$ in $Q^P$ where $h^p : Q^p \to P^P$.

(2) We say a morphism of schemes with integral log. str.'s $f : (X, M) \to (Y, N)$ is exact if the homomorphism $(f^*N)_x \to M_x$ is exact for any $x \in X$.

Following facts are proved easily. Exact morphisms are stable under composition. For fine log. str.'s, exact morphisms are stable under base changes in the category of schemes with fine log. str.'s in the sense of (2.8). An integral morphism is exact. If $f$ is exact, the homomorphism $f^*N \to M$ is injective. (This last fact shows that a closed immersion (3.1) between schemes with integral log. str.'s is exact if and only if it is an exact closed immersion in the sense of (3.1.).)

Now we consider characteristic $p$.

**Definition (4.7).** Let $p$ be a prime number. For a scheme $X$ over $\mathbb{F}_p = \mathbb{Z}/p\mathbb{Z}$ and a log. str. $M$ on $X$, we define the absolute Frobenius $F_{(X,M)} : (X, M) \to (X, M)$ as follows. The morphism of schemes underlying $F_{(X,M)}$ is the usual absolute Frobenius $F_X : X \to X$, and the homomorphism $F_X(M) \to M$ is the multiplication by $p$ on $M$ under the canonical identification of $F_X^{-1}(M)$ with $M$. 
Definition (4.8). Let \( f : (X, M) \to (Y, N) \) be a morphism of schemes with integral log. str.'s. Assume \( Y \) is a scheme over \( \mathbb{F}_p \) with \( p \) a prime number. We say that \( f \) is of Cartier type if \( f \) is integral and the morphism \((f, F_{(X,M)})\) from \((X, M)\) to the fiber product of

\[
\begin{array}{c}
(X, M) \\
\downarrow f \\
(Y, N) \xrightarrow{F_{(Y,N)}} (Y, N)
\end{array}
\]

is exact.

For example, \( f \) is of Cartier type if \( f \) has locally a chart of the form \( Q = N, P = N'(r \geq 1) \), and \( Q \to P \) is the diagonal map. (This happens in the semi-stable reduction situation (3.7)(2).)

Morphisms of Cartier type are stable under compositions and base changes.

(4.9). Let \( p \) be a prime number and let \( f : (X, M) \to (Y, N) \) be a morphism of schemes with integral log. str.'s over \( \mathbb{F}_p \). We say \( f \) is weakly purely inseparable if the following (i)-(iii) are satisfied.

(i) The map \( X \to Y \) of underlying topological spaces is a homeomorphism.

(ii) For \( x \in X \) and \( a \in M_x \), there exists \( n \geq 0 \) such that \( a^n \in \text{Image}(f^{-1}(N)_x) \).

(iii) If \( x \in X \) and if \( a, b \in f^{-1}(N)_x \) have the same image in \( M_x \), \( a^n = b^n \) for some \( n \geq 0 \).

We say \( f \) is purely inseparable if it is exact and weakly purely inseparable.

Proposition (4.10). Let \( f : (X, M) \to (Y, N) \) be a morphism of schemes with fine log. str.'s.

1. Assume that for any \( x \in X \) and \( a \in M_x \), there exists \( n \geq 1 \) such that \( a^n \in \text{Image}(f^{-1}(N)_x) \). Then, etale locally on \( X \), \( f \) has a factorization \( f = f'f'' \) such that \( f' \) is an etale morphism of schemes with fine log. str.'s and \( f'' \) is exact.

2. Assume \( Y \) is a scheme over \( \mathbb{F}_p \) for a prime number \( p \) and \( f \) is weakly purely inseparable (4.9). Then \( f \) has a unique factorization \( f = f'f'' \) such that \( f' \) is an etale morphism between schemes with fine log. str.'s and \( f'' \) is purely inseparable (4.9).

Proof:

Locally on \( X \), \( f \) factors through a morphism \( h(Q) \) (resp. \( h(N) \) satisfying the hypotheses.

(i) For \( a \in A \) and \( b \in B \), \( a^n = b^n \) if and only if \( a_b^n = b_a^n \).

Let \( Q' := \text{Spec}(\mathbb{Z}[Q']) \).

and endow \( X \) and \( Y \) with \( \text{Spec}(\mathbb{Z}[Q']) \).

\( f' : (X, M) \to (Y, N) \) write the homomorphism \( h(Q) \).

\( b \in ((f' \circ h(N))_x) \) for some \( c, d \in F_x \) such that \( e^n = a^n \).

We have finished the proof.

Lemma 4.11. Let \( f : (X, M) \to (Y, N) \) be a morphism of schemes with fine log. str.'s and \( t \) is an isomorphism.
Proof. In the situation of (1) (resp. (2)), it is easily seen that etale locally on $X$, there exists a chart $(P_X \to M, Q_Y \to N, h : Q \to P)$ of $f$ satisfying the following condition (i) (resp. (i) and (ii)).

(i) For any $a \in P$, there exists $n \geq 1$ (resp. $n \geq 0$) such that $a^n \in h(Q)$. (resp. $a^{n^2} \in h(Q)$).
(ii) For any $a, b \in Q$ such that $h(a) = h(b)$, there exists $n \geq 0$ such that $a^{n^2} = b^{n^2}$.

Let $Q' = (h^{ep})^{-1}(P)$ where $h^{ep} : Q^{ep} \to P^{ep}$, let

$$Y' = Y \times_{\text{Spec}(Z[Q'])} \text{Spec}(Z'[Q'])$$

and endow $Y'$ with the inverse image $N'$ of the canonical log. str. of $\text{Spec}(Z'[Q'])$. Then, $f' : (Y', N') \to (Y, N)$ is etale by (3.5). We prove that $f'' : (X, M) \to (Y', N')$ is exact. Note that $Q' \to P$ is exact. Let $x \in X$, and write the homomorphisms $P \to M_x, Q' \to (f''*N')_x, Q' \to P, (f''*N')_x \to M_x$ by $s, t, h', g$, respectively. Our task is to prove that if $a, b \in (f''*N')_x$ and $g(a) \in g(b)M_x$, then $a \in b(f''*N')_x$. We may assume $a = t(a_0), b = t(b_0)$ for some $a_0, b_0 \in Q'$. We have $h'(a_0)c = h'(b_0)d$ for some $c, d \in P$ such that the image of $c$ in $M_x$ belongs to $\mathcal{O}_{X, x}$. Take $n \geq 1$ such that $c^n = h'(e), e \in Q'$. Then, $h'(a_0e) = h'(b_0)c^{n-1}d$. Since $h'$ is exact, we have $a_0e \in b_0Q'$. Since $s(e) \in \mathcal{O}_{X, x}$, we have $a \in b(f''*N')_x$. This completes the proof of (1). Furthermore, in the situation of (2), $f''$ is weakly purely inseparable as is easily seen, and we obtain the local existence of the factorization in (2). It remains to prove the uniqueness of the factorization in (2), from which the global existence follows from the local existence. Assume we have two factorizations $(X, M) \to (Y', N') \to (Y, N)$ and $(X, M) \to (Y', N') \to (Y, N)$ of $f$ satisfying the condition stated in (2). Let $q_i : ((Y', N'_i) \times_{(Y, N)} (Y', N'_i))^{\text{unr}} \to (Y', N'_i)$ be the projections ($i = 1, 2$). Then, $q_i$ is etale and purely inseparable. Hence $q_i$ is an isomorphism by the following (4.11)(which we apply to the case where $s$ and $t$ are isomorphisms). This proves the uniqueness.

**Lemma (4.11).** Let $p$ be a prime number and let

$$
\begin{array}{ccc}
(T', L') & \rightarrow & (X, M) \\
\downarrow & & \downarrow \\
(T, L) & \rightarrow & (Y, N)
\end{array}
$$

be a commutative diagram of schemes with fine log. str.'s over $\mathbb{F}_p$ such that $i$ is purely inseparable, and such that $f$ is etale. Then, there exists a unique morphism $h : (T, L) \to (X, M)$ such that $hi = s$ and $fh = t$.

Proof. By taking a chart of $f$ satisfying the condition (3.5.2), the proof proceeds just as the proof of (3.4).

**Theorem** (4.12) (Cf. [DI], [H2].) Let $p$ be a prime number and let $f : (X, M) \to (Y, N)$ be a smooth morphism of schemes with fine log. str.'s over $\mathbb{F}_p$. Let $f' : (X', M') \to (Y, N)$ be the base change of $f$ by the absolute frobenius $F_{(Y, N)} : (Y, N) \to (Y, N)$, let

$$(X, M) \xrightarrow{F} (X', M') \to (X, M)$$

be the factorization of $F_{(X, M)}$ characterized by the property $f = f'F$, and consider the factorization

$$(X, M) \xrightarrow{g} (X'', M'') \xrightarrow{h} (X', M')$$

of $F^{int} : (X, M) \to (X', M')^{int}$ given by (4.10)(2).

1. Assume $f$ is smooth. Let $s$ be the composite morphism $(X'', M'') \to (X', M') \to (X, M)$. Then we have a canonical isomorphism of $\mathcal{O}_X$-modules

$$C^{-1} : \omega_{X''/Y}^{q} \to \mathcal{O}^q(\omega_{X/Y})$$

for any $q \in \mathbb{Z}$ characterized by

$$C^{-1}(ad \log(s^*(b_1)) \wedge \cdots \wedge d \log(s^*(b_q)))$$

$$= g^*(a) d \log(b_1) \wedge \cdots \wedge d \log(b_q)$$

($a \in \mathcal{O}_{X''}, b_1, \ldots, b_q \in M$).

2. Assume $f$ is smooth and integral. Assume we are given a scheme with a fine log. str. $(\bar{Y}, \bar{N})$ such that $\bar{Y}$ is flat over $\mathbb{Z}/p^2\mathbb{Z}$, and an isomorphism

$$(Y, N) \cong (\bar{Y}, \bar{N}) \times_{\spec(\mathbb{Z}/p^2\mathbb{Z})} \spec(\mathbb{F}_p)$$

where $\spec(\mathbb{F}_p)$. Then, there exist classes of smooth, or smooth and integral in the derived category.

(i) $f$ is smooth and integral in this case.

(ii) The base change of $f$ is smooth and integral in $(X', M')$.

(iii) Etale base change of $(X', M')$.

Then, there is a commutative diagram

$$\begin{array}{ccc}
(X, M) & \xrightarrow{g} & (X'', M'') \\
\downarrow & & \downarrow \\
(X', M') & \xrightarrow{h} & (X', M')
\end{array}$$

satisfies $E_f^{!}$ and $f^{!}$ (classically smooth and integral morphisms) change the values of canonical maps under the $R^f$ modules $\mathcal{F}$.
where \( \text{Spec}(\mathbb{Z}/p^n\mathbb{Z}) \) and \( \text{Spec}(\mathbb{F}_p) \) are endowed with trivial log. str.'s. Then, there exists a canonical bijection between the set of all isomorphism classes of smooth liftings of \((X^\mu, M^\mu)\) over \((\tilde{Y}, \tilde{N})\) (3.14) and the set of all splittings of \( \tau \cong \bigoplus_1 \omega_{X/Y}^{[1]} \) in the derived category of the category of \( \mathcal{O}_X \)-modules (cf. [DI] Section 3). If a smooth lifting of \((X, M)\) over \((\tilde{Y}, \tilde{N})\) exists, there is an isomorphism

\[
\tau_{<p} \omega_{X/Y} \cong \bigoplus_{0 \leq i < p} \omega_{X^\mu/Y}^{[i]}[1]
\]

in the derived category of the category of \( \mathcal{O}_X \)-modules.

(3) Assume the following (i)-(iii).

(i) \( f \) is smooth and of Cartier type. (Note that \((X^\mu, M^\mu) = (X', M')\) in this case.)

(ii) The underlying morphism \( X \to Y \) is proper.

(iii) Etale locally on \( Y \), there exist \((\tilde{Y}, \tilde{N})\) as in (2) and a smooth lifting of \((X', M')\) over \((\tilde{Y}, \tilde{N})\).

Then, the Hodge spectral sequence

\[
E_1^{i,j} = R^i f_* \omega_{X/Y}^{j} \Rightarrow R^{i+j} f_* \omega_{X/Y}
\]

satisfies \( E_1^{i,j} = E_\infty \) for \( s, t \) such that \( s + t < p \). Furthermore, the \( \mathcal{O}_Y \)-modules \( R^q f_* \omega_{X/Y} \) for \( q < p \) are locally free and commute with any base changes.

**Proof.** Since the proof is a simple modification of those given in [DI] (classically smooth case) and in [II] (the case of morphisms of "semi-stable reduction type" between smooth schemes), we give here only the proof of the Cartier isomorphism (4.12)(1), and left the other part of the proof to the reader. (As in [II], the other part is deduced from (1) and (3.14) by the arguments in [DI].) I just note that the assumption \( f \) is integral in (2) is used to have the flatness over \( \mathbb{Z}/p^n\mathbb{Z} \). (4.5) of smooth liftings of \((X^\mu, M^\mu)\). Now we prove (1). By a standard argument, we may assume that there is a cartesian diagram

\[
\begin{array}{ccc}
X & \to & \text{Spec}(\mathbb{F}_p[\mathbb{P}]) \\
\downarrow & & \downarrow \\
Y & \to & \text{Spec}(\mathbb{F}_p[\mathbb{Q}])
\end{array}
\]

where \( P, Q \) are finitely generated integral monoids with a homomorphism \( Q \to P \) such that \( Q^{\text{gp}} \to P^{\text{gp}} \) is injective and the torsion part of \( P^{\text{gp}}/Q^{\text{gp}} \) is of order invertible on \( Y \), and \( M \) and \( N \) are the inverse images of the canonical log. str.'s, respectively. Let \( H \) be the submonoid of \( P \) containing \( Q \) defined by

\[
H = \{ a \in P; a = b^{nc} \text{ in } P^{\text{gp}} \text{ for some } b \in P^{\text{gp}} \text{ and } c \in Q^{\text{gp}} \}.
\]

Then we have

\[
X' = \{ Y \times_{\text{Spec}(\mathbb{F}_p[x])} \text{Spec}(\mathbb{F}_p[H]).}
\]

In this identification, \( X' \to X \) (resp. \( X'' \to Y \), resp. \( X \to X'' \)) is given by

\[
F_{(Y,H)} \times (a \mapsto a^p; P \to H); Y \times_{\text{Spec}(\mathbb{F}_p[x])} \text{Spec}(\mathbb{F}_p[H]) \to Y \times_{\text{Spec}(\mathbb{F}_p[x])} \text{Spec}(\mathbb{F}_p[H]) \to Y, \text{ resp. id.} \times (H \to P); Y \times_{\text{Spec}(\mathbb{F}_p[x])} \text{Spec}(\mathbb{F}_p[H]) \to Y \times_{\text{Spec}(\mathbb{F}_p[x])} \text{Spec}(\mathbb{F}_p[H]).}
\]

For \( v \in P^{\text{gp}}/Q^{\text{gp}} \otimes_{\mathbb{F}_p} \mathbb{F}_p \), let \( E_v \) be the \( \mathbb{F}_p \)-submodule of \( \mathbb{F}_p[H] \) generated by elements of \( P \) which belong to \( v \), and define the complex \( C_v \) by

\[
C_v = \mathcal{O}_Y \otimes_{\mathbb{F}_p[x]} E_v \otimes_{\mathbb{F}_p} \Lambda^q_{\mathbb{F}_p}((P^{\text{gp}}/Q^{\text{gp}}) \otimes \mathbb{F}_p)
\]

with the differential \( C_v \to C_v^{q+1} \) induced by

\[
\Lambda^q_{\mathbb{F}_p}((P^{\text{gp}}/Q^{\text{gp}}) \otimes \mathbb{F}_p) \to \Lambda^{q+1}_{\mathbb{F}_p}((P^{\text{gp}}/Q^{\text{gp}}) \otimes \mathbb{F}_p); \quad a \mapsto v \wedge a.
\]

We have

\[
\omega_{X'/Y} = \bigoplus_v C_v.
\]

The complex \( C_v \) is acyclic if \( v \neq 0 \), and so \( \omega_{X'/Y} \) is quasi-isomorphic to \( C_0 \).

On the other hand, the differential of \( C_0 \) is zero, \( E_0 = \mathbb{F}_p[H] \), and

\[
C_0^q = \mathcal{O}_Y \otimes_{\mathbb{F}_p[x]} \mathbb{F}_p[H] \otimes_{\mathbb{F}_p} \Lambda^q_{\mathbb{F}_p}((P^{\text{gp}}/Q^{\text{gp}}) \otimes \mathbb{F}_p) \cong \omega_{X'/Y}^q
\]

(cf. (1.8)).

\textbf{Remark (4.13).} In (4.12)(1), if \( Y = \text{Spec}(k) \) for a field \( k \) and \( N \) is the trivial log. str., and if \( X \) is normal, \( X'' \) coincides with the normalization of \( X' \).
5. Crystalline sites. A fact for log. str.'s which is different from the classical facts is that the crystalline cohomology theory is easier than the $l$ (≠ char.)-adic etale cohomology theory. (I have not yet a good definition of the etale site for a log. str. A related problem is to define the $K$-group of a scheme with a log. str.)

(5.1) As a base, we take a 4-ple $(S, L, I, \gamma)$ where $S$ is a scheme such that $O_S$ is killed by a nonzero integer, $L$ is a fine log. str. on $S$, $I$ is a quasi-coherent ideal on $S$, and $\gamma$ is a PD (=divided power) structure on $I$.

(5.2) Let $(S, L, I, \gamma)$ be as above, let $(X, M)$ be a scheme with a fine log. str. over $(S, L)$ such that $\gamma$ extends to $X$. Then, we define the crystalline site $(X, M)/(S, L, I, \gamma)$ by

- For $P \in \text{Spec}(F_p[H])$ and $\nu \in \mathcal{O}_S^\times$, $(Y, \nu)$ is given by
  - $Y \times_{\text{Spec}(F_p[H])} \text{Spec}(O_{\nu}^\times F_p)$ where $\mathfrak{m}$ is the maximal ideal of $\mathcal{O}_{\nu}$ and $\nu$ is a PD structure on $\mathfrak{m}$ generated by $\nu$ and $F_p$.
  - $\nu \cdot a \mapsto \nu \cdot a$.

The structure sheaf $O_{X/S}$ on $(X/S)^{cr, PD}$ is defined by

$$O_{X/S}(U, T, M_T, i, \delta) = \Gamma(T, O_T).$$

We sometimes abbreviate $(U, T, M_T, i, \delta)$ simply as $T$. We sometimes denote $\gamma_\nu(a)$ and $\delta_\nu(a)$ as $a^{[n]}$.

We have the following fact by applying (1.4.1) to $U \to T$; if $g : T' \to T$ is a morphism in $(X/S)^{cr, PD}$, $g^*(M_T) \to M_{T'}$ is an isomorphism.

We have a logarithmic version of the PD-envelope:

**Proposition (5.3).** Let $(S, I, \gamma)$ be as in (5.1). (We forget $L$ here). Let $\mathcal{C}$ be the category of closed immersions (3.1) $i : (X, M) \to (Y, N)$ of schemes with log. str.'s over $S$ such that $M$ is fine and $N$ is coherent. (By definition, a morphism $i' \to i$ is a commutative diagram

$$\begin{array}{c}
(X', M') \xrightarrow{i'} (Y', N') \\
\downarrow \quad \downarrow \\
(X, M) \xrightarrow{i} (Y, N)
\end{array}$$

is a morphism in $\mathcal{C}$.)
over $S$.) Let $\mathcal{C}'$ be the category of pairs $(i, \delta)$ where $i$ is an exact closed immersion $(3.1) (X, M) \rightarrow (Y, N)$ of schemes with fine log. str.'s over $S$ and $\delta$ is a PD-structure on the ideal of $Y$ defining $X$ which is compatible with $\gamma$. Then, the canonical functor $\mathcal{C}' \rightarrow \mathcal{C}$ has a right adjoint $\gamma$.

Definition (5.4). In (5.3), let $i : (X, M) \rightarrow (Y, N)$ be an object of $\mathcal{C}$ and let $(\tilde{i}, \tilde{\delta}) : (\tilde{X}, \tilde{M}) \rightarrow (\tilde{Y}, \tilde{N})$, $\delta$ be the result of applying the right adjoint functor to $i$. We call $(\tilde{i}, \tilde{\delta})$ (or sometimes $(\tilde{Y}, \tilde{N})$) the PD-envelope of $(X, M)$ in $(Y, N)$ with respect to $\gamma$, and denote it by $D_{(X, M)}((Y, N)/(S, I, \gamma))$ (or simply by $D_{(X, M)}(Y)$).

(5.5). The construction of the PD-envelope given below shows the following facts:

(5.5.1). If $i$ is an exact closed immersion, $D_{(X, M)}(Y)$ coincides with the usual PD-envelope $D_X(Y)$ endowed with the inverse image of $N$.

(5.5.2). If $\gamma$ extends to $Y$, $(\tilde{X}, \tilde{M}) \rightarrow (X, M)$ is an isomorphism.

(5.5.3). $\tilde{M}$ always coincides with the inverse image of $M$.

(5.6). Proof of (5.3). We construct $(\tilde{i}, \tilde{\delta})$ of (5.4). We may assume $N$ is fine, since $(\tilde{i}, \tilde{\delta})$ for $(X, M) \rightarrow (Y, N)$ is the same thing with $(\tilde{i}, \tilde{\delta})$ for $(X, M) \rightarrow (Y, N)^{\text{int}}$ (2.7). We may work etale locally, and hence we have a factorization $i = g i'$ with $i' : (X, M) \rightarrow (Z, M_Z)$ an exact closed immersion and $g$ etale (4.10)(1). Let $(\tilde{i} : \tilde{X} \rightarrow D, \tilde{\delta})$ be the PD-envelope of $i'$ with respect to $\gamma$ in the usual sense, and endow $\tilde{X}$ (resp. $D$) with the inverse image $\tilde{M}$ (resp. $M_D$) of $M$ (resp. $M_Z$). It is not hard to see that $(\tilde{i} : (\tilde{X}, \tilde{M}) \rightarrow (D, M_D), \tilde{\delta})$ has the desired universal property.

Example (5.7). Let $k$ be a field of characteristic $p > 0$, let $X = \text{Spec}(k[T])$, $Y = \text{Spec}(k[T_1, T_2])$, $X \rightarrow Y$ by $T_i \mapsto T_i (i = 1, 2)$. Endow $X$ (resp. $Y$) with log. str. $M$ (resp. $N$) corresponding to the divisor "$T = 0"$ (resp. "$T_1 = 0" \cup "T_2 = 0"$). Take the base $S = \text{Spec}(k)$, $I = (0)$. Then the PD-envelope $D_{(X, M)}(Y)$ is the usual PD-envelope of $X$ in $Z = \text{Spec}(k[T_1, T_2, T_1T_2^{-1}, T_2T_1^{-1}]) = \text{Spec}(k[T_1, V, V^{-1}]) (V = T_1T_2^{-1}, V \mapsto 1$ on $X)$ endowed with the inverse image of the log. str. $M_2$ on $Z$ corresponding to the divisor "$T_1 = 0" (= "T_2 = 0")$. Indeed, the closed immersion $(X, M) \rightarrow (Y, N)$ is not exact, but $(X, M) \rightarrow (Z, M_Z)$ is an exact closed immersion and $(Z, M_Z) \rightarrow (Y, N)$ is etale.

Remark (5.8). We can define a PD-structure $\delta$ on $X$ so that $\text{Def}(X) = \text{Def}(X/M_2)$ for $X$ a fine log. str. $X$ is defined by a morphism $f : (X, M) \rightarrow (Z, M_Z)$. Then, $(X, M) \rightarrow (Y, N)$ extends this morphism via the diagonal $\Delta : X \rightarrow X \times_S X$ on $X$, if we define $\Delta^* \gamma = \gamma^* \delta$.

(5.9). Let $H$ be a commutative group, $\mathcal{C}(\Delta)$ be a category of schemes $X$ over $S$ with log. str. $M$ and $\Delta : X \rightarrow X \times S$.

(5.10). Let $X$ be a commutative group, $\mathcal{C}(\Delta)$ be a category of schemes $X$ over $S$ with log. str. $M$ and $\Delta : X \rightarrow X \times S$. Then, $X$ has the PD-structure $\delta$ if and only if $\Delta$ has the PD-structure $\tilde{\delta}$.
LOGARITHMIC STRUCTURES

Remark (5.8). Let \((S, L)\) be as in (5.1) (we forget here \(I\) and \(\gamma\)). We can define the \(n\)-th infinitesimal neighbourhood in the logarithmic sense as follows, similarly to the PD-envelopes. For \(n \geq 0\), let \(\mathcal{C}_n\) be the category of exact closed immersions \((X, M) \to (Y, N)\) of schemes over \((S, L)\) such that \(X\) is defined in \(Y\) by an ideal \(I\) with the property \(I^{n+1} = 0\). Then the canonical functor \(\mathcal{C}_n \to \mathcal{C}\) (\(\mathcal{C}\) is as in (5.3)) has a right adjoint. Indeed, let \((Z, M_Z)\) be as in (5.6), and let \(D\) be the \(n\)-th infinitesimal neighbourhood of \(X\) in \(Z\) in the usual sense endowed with the inverse image \(M_D\) of \(M_Z\). Then, \((X, M) \to (D, M_D)\) is the desired universal object. In the case of the diagonal embedding \((X, M) \to (Y, N) = (X, M) \times_{(S, L)} (X, M)\) with \(n = 1\), if we denote by \(J\) the ideal of \(X\) in \(D\), we have

\[
\omega_{X/S}^1 \cong J/J^2.
\]

(5.9). We have the functoriality of the crystalline topoi. Let

\[
\begin{array}{ccc}
(X', M') & \xrightarrow{f} & (X, M) \\
\downarrow & & \downarrow \\
(S', L', I', \gamma') & \longrightarrow & (S, L, I, \gamma)
\end{array}
\]

be a commutative diagram where the assumptions of (5.1) (5.2) are satisfied by both \((X, M)/(S, L, I, \gamma)\) and \((X', M')/(S', L', I', \gamma')\). Then we have the morphism of topoi

\[
f_{\text{cryst}} : (X'/S')_{\text{cryst}}^{-} \to ((X/S)_{\text{cryst}})^{-}
\]

(the \(-\) denote the topos associated to sites) characterized by

\[
f_{\text{cryst}}(\mathcal{F})(U, T, M_T, i, \delta) = \text{Mor}(U, T, M_T, i, \delta)^{-}, \mathcal{F})
\]

where \((U, T, M_T, i, \delta)^{-}\) is the sheaf on \((X'/S')_{\text{cryst}}^{-}\) whose value in \((U', T', M_{T'}^{-}, i', \delta')\) is the set of all pairs \((g, h)\) of morphisms \(g : (U', M') \to (U, M), h : (T', M_{T'}^{-}) \to (T, M_T)\) for which the diagram

\[
\begin{array}{cccc}
(X', M') & \xrightarrow{f} & (U', M') & \xrightarrow{g} & (T', M_{T'}^{-}) \longrightarrow & (S', L') \\
\downarrow & & \downarrow & & \downarrow \\
(X, M) & \xrightarrow{h} & (U, M) & \xrightarrow{h} & (T, M_T) \longrightarrow & (S, L)
\end{array}
\]

is commutative.

We may assume \(N\) algebraic, regular along with \((i, \delta)\) for \((X, M)\), and hence we have a unique exact closed immersion \(i'\) of \(X\) into \(\text{PD-envelope of } i'\) with \(\text{PD-envelope of } i'\) \((D, M_D)\) with the inverse image \(M_D\). We see that \((i : (X, M) \to (D, M_D))\) is the desired universal object.
commutes and such that $h$ commutes with $\delta$ and $\delta'$.

The proof of the fact $f_{\text{crys}}$ determines a morphism of topoi (i.e. $f_{\text{crys}}$ has a left adjoint which commutes with finite inverse limits) is proved by the same way as in the classical theory of crystalline topoi ([B] Chapter 3, Section 2), by using the notion (5.4) of PD-envelopes.

6. Crystals and crystalline cohomology. In this section, let $(S, L, I, \gamma)$ be as in (5.1) and let $f : (X, M) \to (S, L)$ be a morphism of schemes such that $M$ is fine and $\gamma$ extends to $X$.

**Definition (6.1).** A crystal on $(X/S)^{\log}_{\text{crys}}$ is a sheaf of $\mathcal{O}_{X/S}$-modules $\mathcal{F}$ on $(X/S)^{\log}_{\text{crys}}$ satisfying the following condition: For any morphism $g : T' \to T$ in $(X/S)^{\log}_{\text{crys}}$, if we denote by $\mathcal{F}_T$ and $\mathcal{F}_{T'}$ the sheaves on $T_{\text{et}}$ and $T_{\text{et}}'$ induced by $\mathcal{F}$ respectively, $g^*(\mathcal{F}_T) \to \mathcal{F}_{T'}$ is an isomorphism.

**Theorem (6.2).** Let $(Y, N)$ be a scheme with a fine log. str. which is smooth over $(S, L)$, and let $(X, M) \to (Y, N)$ be a closed immersion (3.1). Denote the PD-envelope of $(X, M)$ in $(Y, N)$ as $(D, M_D)$. Then, the following two categories (a) (b) are equivalent.

(a) The category of crystals on $(X/S)^{\log}_{\text{crys}}$.

(b) The category of $\mathcal{O}_D$-modules $\mathcal{M}$ on $D_{\text{et}}$ endowed with an additive map

$$\nabla : \mathcal{M} \to \mathcal{M} \otimes_{\mathcal{O}_Y} \omega^1_{Y/S}$$

having the following properties (i)–(iii).

(i) $\nabla(ax) = a\nabla(x) + x \otimes da$ for $a \in \mathcal{O}_D$ and $x \in \mathcal{M}$.

(ii) The composite

$$\mathcal{M} \to \mathcal{M} \otimes_{\mathcal{O}_Y} \omega^1_{Y/S} \to \mathcal{M} \otimes_{\mathcal{O}_Y} \omega^2_{Y/S}$$

is zero, where we extend $\nabla$ to

$$\mathcal{M} \otimes_{\mathcal{O}_Y} \omega^q_{Y/S} \to \mathcal{M} \otimes_{\mathcal{O}_Y} \omega^{q+1}_{Y/S};$$

$$x \otimes \omega \mapsto \nabla(x) \wedge \omega + x \otimes d\omega.$$
(iii) Let $x \in X$ and let $t_i (1 \leq i \leq r)$ be elements of $M_x$ such that $(d \log(t_i))_1 \neq 0$. Then, for any $i$ and for any $a \in \mathcal{M}_x$, there exist $m_1, \ldots, m_k, n_1, \ldots, n_k \in \mathbb{N}$ such that

\[ \prod_{1 \leq i \leq r, 1 \leq j \leq k} (\nabla_{t_i}^{\log} - m_j)^{n_j}(a) = 0. \]

Here $\nabla_{t_i}^{\log}$ is defined by: if $\nabla(a) = \sum_{1 \leq i \leq r} a_i \otimes d \log(t_i)$, then $\nabla_{t_i}^{\log}(a) = a_i$.

(1) It is proved as in the classical case, that if the condition (iii) holds for one choice of $(t_i)_{1 \leq i \leq r}$, then it holds for any choice of $(t_i)_{1 \leq i \leq r}$.)

**Remark (6.3).** If $t_i \in \mathcal{O}_{X,x}$ and $\nabla_{t_i}$ denotes $t_i^{-1} \nabla_{t_i}^{\log}$, then

\[ (\nabla_{t_i})^a = t_i^{-n} \prod_{0 \leq j \leq n-1} (\nabla_{t_i}^{\log} - j). \]

Thus, the condition (b) (iii) in (6.2) is the natural logarithmic version of the classical notion of the "quasi-nilpotence" ([B] Chapter 2, Section 4.3).

**Theorem (6.4).** Let $(X, M), (Y, N)$ and $D$ be as in (6.2), let $\mathcal{F}$ be a crystal on $(X/S)^{\log}_{\text{cryst}}$ and let $\mathcal{M}$ be the corresponding $\mathcal{O}_D$-module with $\nabla$.

Then,

\[ Ru^{\log}_{X/S}((\mathcal{F})) \cong \mathcal{M} \otimes_{\mathcal{O}_Y} \omega_{X/S}. \]

Here $u^{\log}_{X/S}$ is the canonical morphism $((X/S)^{\log}_{\text{cryst}})^{-} \rightarrow (X_a)^{-}$ characterized by

\[ (u^{\log}_{X/S})_a(\mathcal{F})(U) = \text{the global section of } \mathcal{F} \text{ on } (U/S)^{\log}_{\text{cryst}} \]

for a sheaf $\mathcal{F}$ on $(X/S)^{\log}_{\text{cryst}}$.

For the proofs of (6.2) and (6.4), the following (6.5) is essential.

**Proposition (6.5).** Under the assumption of (6.2), let $(D', M_{D'})$ be the PD-envelope (5.4) of the diagonal morphism $(X, M) \rightarrow (Y, N) \times_{(X, Z)} (Y, N)$, and let $p_1, p_2 : (D', M_{D'}) \rightarrow (D, M_D)$ be the first and the second projections, respectively. Let $x \in X$, take $t_1, \ldots, t_r \in N_x$ such that $(d \log(t_i))_{1 \leq i \leq r}$ is a basis of $\omega_{X/S,x}$, and let $u_i (1 \leq i \leq r)$ be the elements of $\text{Ker}(\mathcal{O}_{D', x}^{\log} \rightarrow \mathcal{O}_{X,x}^{\log}) \subset (M_{D'})_x$ defined by $p_1^*(t_i) = p_2^*(t_i) u_i$ (the existence...
of \( u_i \) follows from \((M_{D^{*}})_{\bar{x}}/\mathcal{O}_{D^{*},\bar{x}} \cong M_{\bar{x}}/\mathcal{O}_{\bar{x},\bar{x}}\). Then we have the description of \( D' \)

\[ \mathcal{O}_{D^{*},\bar{x}}(T_1, \ldots, T_r) \cong \mathcal{O}_{D^{*},\bar{x}}; \quad T_i^{[u_i]} \mapsto (u_i - 1)^{[u_i]} \]

where \( \mathcal{O}_{T,\bar{x}}(T_1, \ldots, T_r) \) denotes the PD-polynomial ring.

\((6.6)\). Proof of (6.5). By the construction of the PD-envelopes in (5.6), we may assume that \((X, M) \to (Y, N)\) is an exact closed immersion. Etale locally at \( x \), take an exact closed immersion \((X, M) \to (Z, M_Z)\) where \( M_Z \) is fine and \((Z, M_Z) \) is etale over \(((Y, N) \times_{(S, L)} (Y, N))^{\text{et}}\)

(4.10)(1). Let \( q_j : Z \to Y (i = 1, 2) \) be the two projections. Then, the stalks at \( \bar{x} \) of the sheaves \( M_Z \) and \( q_i^*(N)(i = 1, 2) \) coincide. So, by replacing \( Z \) by an etale neighbourhood of \( \bar{x} \to Z \), we may assume that \( M_Z = q_i^*N \) (\( i = 1, 2 \)). Then, \( q_i \) are smooth in the usual sense by (3.8). Since \( D' \) (resp. \( D^{*} \)) is the usual PD-envelope of \( X \) in \( Y \) (resp. \( Z \)), and since \( q_i^*(t_i)^{-1} q_i^*(t_i) - 1 \) (\( 1 \leq i \leq r \)) form a smooth coordinate of \( Z \) over \( Y \) with respect to (say) \( q_1 \) and their restrictions to \( X \) are zero, the statement of (6.5) follows.

\((6.7)\). Proof of (6.2). We follow the classical theory ([B] Chapter 4, Section 1). Let \((M, \nabla)\) be an object of (b). We show how to define the corresponding object of (a). Let \( x \in X \), let \( (t_i) \) be as in (b)(iii), and let \( D' \) and \((u_i)\) be as in (6.5). Then we have an isomorphism at \( \bar{x} \)

\[(6.7.1) \quad \eta : p^*_x \mathcal{M} \cong p^*_x \mathcal{M} ;
\]

\[ 1 \otimes a \mapsto \sum_{n \in \mathbb{N}} \left( \prod_{1 \leq i \leq r} (u_i - 1)^{[u_i]} \right) \otimes \left( \prod_{1 \leq i \leq r, 0 \leq j \leq u_i - 1} (\nabla^k_{n_i} - j) (a) \right) \]

(\( a \in \mathcal{M} \)), which satisfies the "transitivity condition"

\[ p^*_x (\eta) = p^*_x (\eta) p^*_x (\eta) \]

([B] Chapter 2, 1.3.1) on the PD-envelope \( D^{*} \) of \((X, M) \) in \((Y, N) \times_{(S, L)} (Y, N) \times_{(S, L)} (Y, N)\) where \( p_{12}, p_{13}, p_{23} \) are the projections \( D^{*} \to D' \).

Now we obtain an object \( \mathcal{F} \) of (a) from \((\mathcal{M}, \nabla)\) as follows. Let \((U, T, M_T, \delta)\) be an object of \( (X/S)^{\text{et}}_{\text{reg}} \). Then, etale locally on \( T \), \( (X, M) \to (D, M_D) \) is extended to a morphism \( h : (T, M_T) \to (D, M_D) \) over \((S, L)\) by the smoothness of \((Y, N) \to (S, L)\). We define \( \mathcal{F} \) to be \( h^* \mathcal{M} \) etale locally on

\[ T. \]
T. If we have two such \( h_i : (T, M_T) \to (D, M_D) \) \((i = 1, 2)\), they define \( h' : (T, M_T) \to (D', M_D') \) such that \( h_i = p_i h' \), and the isomorphism (6.7.1) induces \( p_i \mathfrak{M} \equiv h' \mathfrak{M} \). Thus \( \mathcal{F} \) is independent of \( h \) and defined globally on \( T \).

Conversely if we have an object \( \mathcal{F} \) of \( (a) \), let \( \mathfrak{M} = \mathcal{F} \). Then, the defining condition of the crystal gives an isomorphism \( \eta : p_i \mathfrak{M} = p_i \mathfrak{M} \) satisfying the "transitivity condition". By writing \( \eta \) in the form

\[
1 \otimes a \mapsto \sum_{n \in \mathbb{N}} \prod_{1 \leq i \leq r} (u_i - 1)^{|u_i|} \otimes \eta_n(a),
\]

we define \( \nabla \) by

\[
\nabla(a) = \sum_{1 \leq i \leq r} \eta_{e_i}(a) \otimes d \log(t_i)
\]

where \( (e_i)_{1 \leq i \leq r} \) is the canonical base of \( \mathbf{N} \).

(6.9). Proof of (6.4). This is also a repetition of the classical argument. For an \( \mathcal{O}_{D'} \)-module \( \mathfrak{M} \) on \( D'_{et} \), let \( L(\mathfrak{M}) \) be the crystal on \((X/S)^{log} \) corresponding to the \( \mathcal{O}_{D'} \)-module \( p_{i}^{\dagger} \mathfrak{M} \) with

\[
\nabla : p_{i}^{\dagger} \mathfrak{M} \to p_{i}^{\dagger} \mathfrak{M} \otimes_{o_{Y}} \omega_{Y/S}^{1} ; \quad a \otimes \nu \mapsto \nu \otimes da
\]

\((a \in \mathcal{O}_{D'}, \nu \in \mathfrak{M}, \text{with } D' \text{ as in } (6.5))\). Here \( d \) is the composite map

\[
\mathcal{O}_{D'} \to \mathcal{O}_{D'} \otimes_{o_{D'}} \omega_{Z/S}^{1} \equiv \mathcal{O}_{D'} \otimes_{o_{Y}} \omega_{Y/S}^{1}
\]

with \( Z \) as in (6.6). The same argument as in the classical theory shows

\[
R(u_{X/S})_{*} L(\mathfrak{M}) = \mathfrak{M},
\]

where we identified \( X_{et} \) with \( D'_{et} \). If \( \mathcal{F} \) is a crystal corresponding to \((\mathfrak{M}, \nabla)\), we have a resolution

\[
\mathcal{F} \to L(\mathfrak{M} \otimes_{o_{Y}} \omega_{Y/S}).
\]

We obtain from this

\[
R(u_{X/S}^{log})_{*} \mathcal{F} \equiv (u_{X/S}^{log})_{*} L(\mathfrak{M} \otimes_{o_{Y}} \omega_{Y/S}) \equiv \mathfrak{M} \otimes_{o_{Y}} \omega_{Y/S}.
\]
The following (6.10) (the base change theorem) and (6.11) (the Künneth formula) are proved by the same method in the classical theory ([IB] Chapter 5, Sections 3 and 4).

**Theorem (6.10).** Assume we are given a commutative diagram

\[
\begin{array}{ccc}
(X', M') & \xrightarrow{g'} & (X, M) \\
\downarrow f & & \downarrow f \\
(Y', N') & \xrightarrow{g} & (Y, N) \\
\downarrow & & \downarrow \\
(S', L', I', \delta) & \xrightarrow{h} & (S, L, I, \delta)
\end{array}
\]

where all the log. str.'s are fine, \( Y \) is quasi-compact, \( f \) is smooth and integral, the underlying morphism \( X \to Y \) of \( f \) is quasi-separated, and the upper square is cartesian. Let \( \mathcal{F} \) be a quasi-coherent crystal on \((X/S)_{\text{log}}\) which is flat over \( \mathcal{O}_{X/S} \). Then, we have a canonical isomorphism

\[
L_{\mathfrak{g}_{\text{crys}}}^\ast (Rf_{\text{crys}}^\ast (\mathcal{F})) \cong Rf_{\text{crys}}^\ast (g'_{\text{crys}}^\ast (\mathcal{F})).
\]

**Theorem (6.12).** Let \( f: (Y, M_Y) \to (X, M_X) \) and \( g: (Z, M_Z) \to (X, M_X) \) be smooth integral morphisms between schemes with fine log. str.'s over \((S, L)\), and assume that \( X \) is quasi-compact and the underlying morphisms \( Y \to X \), \( Z \to X \) are quasi-compact and quasi-separated. Let \((V, M_V)\) be the fiber product of \((Y, M_Y)\) and \((Z, M_Z)\) over \((X, M_X)\) with \( p: (V, M_V) \to (Y, M_Y) \), \( q: (V, M_V) \to (Z, M_Z) \), \( h: (V, M_V) \to (X, M_X) \), and let \( \mathcal{E} \) (resp. \( \mathcal{F} \)) be a quasi-coherent crystal on \((Y/S)_{\text{log}}\) (resp. \((Z/S)_{\text{log}}\)) which is flat over \( \mathcal{O}_{Y/S} \) (resp. \( \mathcal{O}_{Z/S} \)). Then, we have a canonical isomorphism

\[
Rf_{\text{crys}}^\ast (\mathcal{E}) \otimes_{\mathcal{O}_{X/S}}^{L} \mathcal{G}_{\text{crys}}^\ast (\mathcal{F}) \cong Rh_{\text{crys}}^\ast (p_{\text{crys}}^\ast (\mathcal{E}) \otimes_{\mathcal{O}_{Y/S}}^{L} q_{\text{crys}}^\ast (\mathcal{F})).
\]

**Complement 1.** We explain the relation between the log. str. of this note and that of Faltings in [Fa2]. A definition of log. str. equivalent to that of Faltings was found by Deligne ([D]) independently.

The log. str. of Faltings in [Fa2] on a scheme \( X \) is a family \((\mathcal{L}_i, x_i)_{1 \leq i \leq r}\) of invertible sheaves \( \mathcal{L}_i \) on \( X \) and global sections \( x_i \) of \( \mathcal{L}_i \). An equivalent definition (take the dual) given in [D] is that a log. str. on \( X \) is a family \((\mathcal{L}_i, s_i)_{1 \leq i \leq r}\) of invertible sheaves \( \mathcal{L}_i \) on \( X \) and homomorphisms \( s_i : \)

\( \mathcal{L}_i \to \mathcal{O}_X \), \( \mathcal{O}_X \) is a strictly semistable dvr., \( \mathcal{L}_i \) is a sheaf of \( M \)-modules, \( \mathcal{L}_i \to \mathcal{O}_X \) is an \( M \)-module homomorphism, \( \mathcal{L}_i \to \mathcal{O}_X \) is a strict local ring, \( \mathcal{L}_i \to \mathcal{O}_X \) is a strict local ring, and \( s_i \) is a strictly semistable dvr. of \( M \)-module homomorphism.

for some \( P \) in the spectrum of \( M \) with zero ring \( M \) if and only if \( M \) is a D. F. log. str. if and only if \( M \) is a strictly semistable dvr. of \( M \) if and only if \( M \) is a D. F. log. str. if and only if \( M \) is a strictly semistable dvr. of \( M \).
LOGARITHMIC STRUCTURES

\[ \mathcal{L}_i \to \mathcal{O}_X \text{ of } \mathcal{O}_X \text{-modules. To compare with our log. str., we adopt the latter definition of Deligne for it is nearer to our definition, and we call the log. str. } (\mathcal{L}_i, s_i) \text{ in the sense of Deligne the DF. log. str.}

We claim that a DF. log. str. on } X \text{ is equivalent to a pair } (M, t) \text{ of a fine log. str. (in our sense) } M \text{ on } X \text{ and a homomorphism } t : N_X^r \to M/\mathcal{O}_X^r \text{ which lifts etale locally on } X \text{ to a chart } \mathcal{N}_X^r \to M \text{ of } M. \text{ Indeed, for such a pair } (M, t), \text{ we define } (\mathcal{L}_i, s_i) \text{ as follows. Assume } k \text{ is perfect and } \text{char}(k) = p > 0, \text{ and let } W_n(k) \text{ be the ring of Witt}
vectors of length \( n \), and endow \( \text{Spec}(W_n(k)) \) with the log. str. \( N \) associated to \( N \rightarrow W_n(k); 1 \mapsto 0 \). By fixing a prime element \( \pi \) of \( A \), we have morphisms

\[(Y, \tilde{M}) \rightarrow (\text{Spec}(k), \tilde{N}) \rightarrow (\text{Spec}(W_n(k)), N_n)\]

where the second arrow is induced from \( N \rightarrow A; 1 \mapsto \pi \). (Then, \( N \rightarrow \tilde{N} \) is an isomorphism.) Consider the crystalline cohomology of \( (Y, M) \) over the base \( (\text{Spec}(W_n(k)), N_n) \) with the usual PD str. on the ideal \( pW_n(k) \). Then this crystalline cohomology is very important, and serves as the mixed characteristic analogue of the limit Hodge str. \([S]\). For the details and the relation with the de Rham-Witt complex in \([H_2]\), cf. \([HK]\) and \([K']\).
